$s1 <= $s2

BLE $s1, $s2, branch:

slt $t0, $s1, $s2
bne $t0, $zero, branch.
} convert to >= first.

slt $t0, $s2, $s1
beq $t0, $zero, branch
} if !($s1 ≥ $s2),

sub $t1, $s2, $s1
slt $t2, $t1, $zero
beq $t2, $zero, target.

Single cycle vs Multicycle:
- multicycle > single cycle as not all instructions pass through every stage of the datapath.
- multicycles will not grant an N times speedup since not all stages take the same time.
- single cycles are scaled to the longest instruction and the time needed to run it; multicycles will take up the same amount of time as well

Declaring new instructions:
- control signals depend on the type of operations
  → instructions that should not branch cannot set PCSrc = 1
- NOP cannot modify registers/memory
  → cannot branch
  → other control signals can be whatever

N/(N-1)'s complement:
- leftmost bit is sign bit so it has no weight.

Jump Instruction Ranges:
- must be able to reach the next block of instructions (so there are overlaps - 18/19)
- at most 2^{26} (inclusive of the jump)
- only jumps backwards if at the end of the block
- only jumps forwards if at the start of the block
- always jumps to the same location.

C programming:
- structs are <u>not</u> pass by reference
- arrays are pass by reference
- C strings must end with '\0'
- shifting right is sign extending (sometimes)

MIPS conversions:
- always remember to convert from hex to decimal for opcode/funct.

NOT:
- achieved by using double XOR:
  n ^ 1.. ^ 0..

min/max:
- always remember to not touch existing instructions.
- min → max out the smallest then work up (addition)
- max → max out the largest then subtract by blocking out instructions (remember to add back those blocked out)
  ↓
  count how many bits get deprived

ASCII:
- can be found in single hexadecimal

Complements:
- only compute if negative, else use raw value
- A - B = A + (~B)
  ~ compute complement.

Instruction Counting:
- count the number of instructions/loop x loops.
